## EC2.101 - Digital Systems and Microcontrollers

## **End Semester Examination**

Max. Time: 3 Hr

Max. Marks: 70

## CALCULATORS ARE NOT ALLOWED

Numbers in square brackets [x] after a statement show the marks for that question. Numbers in {} brackets are for administrative use. Please ignore.

Q1. Let's say we are working in the ternary system (radix = 3). However, we need to create circuits using Boolean logic for the operations. A simple operation is to add two numbers. Given two 1-digit ternary numbers, design a circuit that produces their sum. [Hint: you will require 2 wires to represent 1-digit of ternary].

[12 marks]{CO-1}

Q2. We are given a serial stream of bits. Within this bit stream, we want to see if there is a 4-bit prime number. Design a circuit that outputs '1' if there is a 4-bit prime number in a given bit stream. The output should be active for one clock cycle upon detection of the prime number. If the next combination of 4 bits is also prime, the output should remain '1'. For example, bit stream 10111 will produce output '1' for two cycles, because 0111 and 1011 are both prime.

[12 marks]{CO-3}

Q3. Most of the arithmetic happens in a computer using 2's complement notation. Suppose we are given two 4-bit numbers in signed 2's complement representation (A and B). Design a circuit to compare them and output (A>B), (A<B), and (A=B).

[12 marks]{CO-2}

Ø4. Perform the following conversions:

X (978)10 = (?)16

27 (73)<sub>8</sub> + (5BC)<sub>16</sub> = (57)<sub>8</sub> + (?)<sub>16</sub>

3/  $(1011)_8 = (?)_{10}$ 

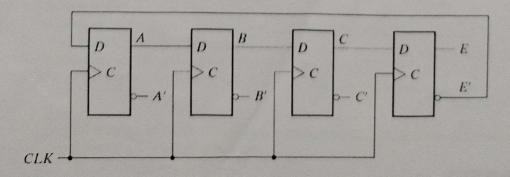

4)  $(110)_2 \times (11011)_2 = (?)_{16}$ 

 $5)/(3.78)_{10} = (?)_2$ 

 $[2x5 = 10 \text{ marks}]\{\text{CO-1}\}\$ 

25. What is the behaviour of the following circuit if clock pulses are applied from a reset state (when all FFs are at zero) [4]? Draw the complete state diagram for the 16 distinct states (including starting in any other state) [4]. In general, if there are k flip-flops in this chain and any arbitrary starting state is chosen, how many clock cycles does it take to make sure we return to the original state [4]?

 $[4+4+4 = 12 \text{ marks}]\{\text{CO-3}\}$ 

Q6. We are required to find the sum of a set of N numbers located in a block of memory starting from location "0x200". The number N itself is stored in location "0x220" (assume N<0x20). Write an assembly level program that computes this sum using our simple 8-bit microcontroller. (Concise instruction set is provided below). Assume your own code starts at memory location "0x000". Provide reasoning for your code.
